Please replace the abstract as follows:

**ABSTRACT**

A schema-based contacts service for Internet access to per-user contact data, wherein access to data is based on each user's identity. The contacts service includes a schema that defines rules and a structure for each user's data, and also includes methods that provide access to the data in a defined way. The contacts schema thus corresponds to a logical document containing the data for each user. The user manipulates (e.g., reads or writes) data in the logical document by data access requests through defined methods. In one implementation, the contacts schemas are arranged as XML documents, and the services provide methods that control access to the data based on the requesting user's identification, defined role and scope for that role. In this way, data can be accessed by its owner, and shared to an extent determined by the owner.
